Pull out testing and anchor bolt tests always entails maximum design load stress testing anticipated in construction and meeting the standards of the industry. This is not destructive testing so the actual loads applied as well as the sample scale of the tests will be determined by our on-site engineers.

The push-pull test is a powerful site characterization technique that has been applied to a wide range of problems in contaminant hydrogeology. The theoretical and practical aspects of push-pull testing were initially developed to characterize groundwater aquifers but the method has now been extended to saturated and unsaturated soils and sediments as well as to surface water bodies.

Key Descriptions. The Push and Release Test was developed as an alternative to the "Pull Test" now included in the United Parkinson's Disease Rating Scale (UPDRS, Item #30). The patient leans back pressing on the hands of the examiner; the examiner then suddenly removes their hands. Scores are based on the patient's correctional response...

A single-well push-pull test is conducted by injecting (push phase) a volume of water containing a tracer into a single well, followed by a non-pumping period (drift phase), and subsequent extracting (pull phase) of groundwater from the same well in order to generate a breakthrough curve (Istok 2013). A single-well push-pull test has the ...
